2001 Perennial Initiation Point Project

Prepared By
Eric Krausz, Ruby Peone, and Sondra Collins
Timber, Fish, and Wildlife Biologists
Colville Confederated Tribes/ Spokane Tribe of Indians

Introduction

During the Forest and Fish discussions the default initiation point of perennial stream flow was established for the eastern Washington watersheds at a basin area of 300 acres. This point would be used to delineate between the type 4/5 break under the present water typing system. Under the new water typing criteria this point will be used to determine the upper most flow of type N (non-fish bearing) waters. Type N waters are further sub-divided into two categories: perennial (Np) segments that do not dry up, and seasonal (Ns) segments that do become dry in a year of normal rainfall. Type Np streams require partial forest buffering and other protections during forest practices (logging, road maintenance) not required for Ns streams.

The Perennial Initiation Point (PIP) Pilot Project was created to collect baseline data supporting adaptive management related to water typing in headwater streams. The field sample protocol for this project was developed in order to identify locations in streams where continuous perennial flow and spatially intermittent perennial flow are found. In addition, the validity of the default 300-acre (eastern WA) basin area was to be tested, addressing one of the L-2 questions on CMER's priority list of unresolved issues. Currently, the West-side default lies at 52 acres. However, Pre-2001 PIP data collected from Hydrologist Curt Veldhuisen of the Skagit System suggested a much lower basin size of 21 acres.

The Data collected for this project was in accordance with the protocol established by the Np Survey Working Group/ In-Stream Advisory Group (ISAG). Additional information resulting from this pilot project includes:

- data suggesting the appropriate sample sizes for the statewide stratification
- suggestions/ recommendations regarding the field sampling protocol
- additional variables related to stream relationships and functions that may add insight on better data stratification.

In addition, the data collected within the 2001 field season may be helpful in the development of the water typing system model and statewide map, which is a habitat based model to determine fish habitat Type F breaks, currently being created for the WADNR Forest Practices Act WAC222-16-030. There will also be a new section of the Forest Practices Board Manual (Section 23) developed to provide technical guidance to

landowners and foresters in determining the upper most headwater spring and/or the upper most extent of Type Np streams.

Eastern Washington is composed of a wide range of regional variability, which contributes to its diverse ecosystems. In order to better understand these complex relationships, data must be collected which is representative of the geographic diversity found in eastern Washington. The random site selection process in this study was designed to account for multiple environmental variables such as: aspect, elevation, geology, soils, vegetation, and precipitation. The TFW Biologists of the Upper Columbia United Tribes (UCUT) including, the Colville Confederated Tribes (CCT) and the Spokane Tribe of Indians (STOI), conducted the PIP surveys'.

Goals and Objectives

The goal of this project is to investigate the appropriateness of the 300-acre basin size demarcation for the point of perennial flow of non-fish bearing waters in eastern Washington. The overall intent of this study was to aid in the development of State Forest Practice Regulations, while streamlining timber harvest operations and maintaining a high level of stream quality related to the management of public resources.

The objectives of this pilot project are consistent with the Scope of Work in Attachment A within the interagency agreement # IAA 02-109 between the Department of Natural Resources and the Colville Confederated Tribes.

Methods

The methods used in this study are in compliance with the Perennial Stream Survey Field Sample Protocol (version 1.21) written by the Np Survey working Group/ In-Stream Advisory Group (ISAG). Sample sites were randomly selected in accordance with option 3 of the sample protocol. Following site selection the Main Thread Survey was performed using the Downstream Method.

CCT GIS coordinates were collected using a handheld Garmin GPS CX and downloaded into a PC using Garmin Mapsource. All coordinates were then converted to a shapefile in association with Arcview 3.2 GIS. Three individual maps were created for each PIP representing a 7.5 minute/1:24000-scale. Due to time constraints, 6 of the CCT off – reservation survey sites do not have aerial photo or vegetation mapping. In addition, the STOI basin mapping does not include vegetation or aerial photos due to discrepancies in map projections. The mapping data includes: National Geographic Seamless USGS Topographic Base Map with DNR stream layers (DNRSTR_83), Aerial Photo/Digital Ortho-quad images (DOQ 1991/1996), and a NRCS/CCT Land Operations soil based vegetation data layer (soils_83). The basin sizes for each PIP were calculated in Arcview by creating a Polygon Theme and digitizing the basin boundaries on top of the USGS Topographic Base Map. Starting from the PIP, a line was drawn to the nearest ridge

following the upper extent of the topography surrounding the basin. The polygon shape was completed when the line tied back into the PIP. The elevations for each PIP were determined using the associated contour lines on the individual USGS Topographic site maps.

STOI captured real-time Global Positioning System (GPS) coordinates using a TSC1 Tremble Navigator. Coordinates were downloaded into a PC using GPS Pathfinder Office Vers 2.70 software support. Differential conversions were run from base station files stored on the STOI GIS base station rover files. The PIP differential corrected files were then exported into Arc View and converted to shape-file format. The shape-file was then delivered to the CCT GIS specialist to determine basin size. As an additional resource, the STOI has their shape-files overlaid onto Arc View background overlay coverage's with WADNR watershed administrative units (lit.cit.), DOE (lit.cit.), USGS 24K Contour (lit.cit.) files and saved into (STOIPIP.apr) project. Other additional resources available from the STOI include: PIP basin vegetations recovered from a variety of scientific citations such as: Zamora 1983, Spokane Tribe Forest Habitat Type (FHA.shp) shape file coverage's, United States Forest Service Regional Ecosystem Office recovered GIS data dictionaries for vegetation of Lake Roosevelt and Pend Oreille and Little Spokane River basins (c115.shp and c116.shp). If no vegetation coverage's were accessible, then sites were confirmed by field observation according to Kovalchik, 2001. (Contact Sandra Collins, TFW Biologist STOI for more information)

The STOI and CCT participated in QA Training and QC Review on September 5th, 2001with Allen Pleus (Forest Practices Coordinator, NWIFC) and Mara McGrath (Botanist, Ecological Land Services, Inc.). In addition, Mara McGrath met both the CCT and the STOI for field survey QA/QC training and review.

STOI & CCT TFW/F&F also participated in on going scientific peer review to the "*Perennial Stream Survey Field Sample Protocol (Vers1.21)*" prepared by the Np Survey Working Group 8/8/01.

Results and Discussion

The PIP survey's began in early August, but were postponed within the lands surrounding the Colville Confederated Tribes due to the extreme fire hazards and regulatory forest restrictions associated with the Virginia Lake Fire. Precipitation levels created drought like conditions limiting access to forested lands within the region. The surveys' resumed in mid-September through mid-October and ended due to seasonal increases in precipitation. The locations of our survey sites spanned from northcentral to northeast Washington (see master map). There was a significant variation between individual survey sites, associated with the changing topography, geology etc., across such a large landscape.

The TFW Biologists of the CCT and the STOI surveyed a total of 21 Perennial Initiation Points in the 2001 field season, averaging approximately 13 hours per PIP. These hours

include: site selection, travel, locating PIP and conducting the field survey. Hours associated with GIS mapping were not included. Basin size was calculated using Arcview 3.2 GIS for all 21 PIP's (see appendix A or Table 1.). The basin sizes varied from 3258.9 acres (Beaver Cr. 1) to 20.8 acres (Deadman Cr.), and averaged 343 acres. However, the average basin size is not a fair representation due to the extreme basin size of Beaver Cr. 1 and Kinkaid Cr. When the 2 smallest and 2 largest basins are eliminated from the average as outliers, the revised average becomes 159 acres. The average elevation including all sites was 3741 feet, and with the 4 outliers eliminated 3640 feet. The elevations associated with each PIP suggest that basin size may be a representation of the elevation at which the PIP is located (see table 1). The two largest basins, Beaver Cr. 1 (3258.9 acres) and Kinkaid Cr. (2461 acres) were both located at approximately 2500 feet or less. This could be analogous to an increase in the available surface area as you move down the side of a mountain. Additional field data may clarify this relationship, adding insight toward stratifying the default basin size with respect to elevation bands. For example, harvest practices occurring at a higher elevation would receive a smaller default basin size than those at a lower elevation.

Table 1. Relationship Between Elevation and Basin Size

(* = outlier)

Two examples that offer insight into the variability with which eastside PIP's can occur during seasonally low flows are Smith and Kinkaid Creek. In the 2001 field season we observed the presence of Brook Trout and Cutthroat Trout immediately below the perennial initiation point at 2 of our surveyed sites. Both of these sites were within the "Ponderosa Pine Zone" at approximately 2500 ft. in elevation.

The first of these sites was Smith Creek, which initiated at a spring, located at the base of a small bowl, approximately 22.2 acres in size (see appendix A). The immediate topography surrounding Smith Creek does not appear to be large enough to support perennial flow. Therefore it is likely that the spring is fed by subsurface water flows related to a larger basin area, not connected by a dry channel, but possibly influenced by geological variables. In addition, Smith Creek goes subsurface where it enters an agricultural area before entering the Nespelem River. There appears to be no associated surface channel present to connect the mouth to the headwaters, and there is no recent record of fish stocking. It is important to consider that the nature of the soils within the Okanogan Highlands (ash and loess), in combination with agricultural water use, can result in a significant drop in local water tables. One possible result of such an event is subsurface stream flow, which may cut off resident fish populations from downstream access. Dry stream channels or other features obstructing fish passage do not rule out the possibility of resident fish populations occurring upstream, especially at lower elevations associated within agricultural lands.

The second site was Kinkaid Creek, which initiated at a point far below the upper most extent of the dry stream channel. The calculated basin size above the Kinkaid Creek PIP was 1202 acres (see Appendix A). Riparian associated vegetation was continuous and the gradient of the dry channel was less than 8%, which suggests the potential for seasonal fish usage during periods of higher water. This is further substantiated by the presence of a 6" Eastern Brook Trout. Kinkaid Creek shows us that selecting August as the primary surveying month may facilitate a larger default basin size due to the PIP occurring farther downstream then it would occur during winter or spring. A repercussion of this idea is the default basin size being larger than necessary, resulting in negative impacts associated with downstream sediment delivery. Machinery associated with forest practices often increases soil density through compaction, resulting in decreased soil porosity. "A reduction in porosity reduces the rate at which water can enter soil, thus increasing the proportion of water flowing over the soil surface" (Singer and Munns 62). The soil that is picked up from this increase in water movement will eventually enter type F (fish bearing) waters.

The relationship between intermittent stream flow and fish/amphibian habitat is of great importance in this study. The idea of delineating default basin sizes, relative to perennial flow, shows little regard for the importance of the seasonal contributions made to downstream habitats by intermittent streams. For example, allochthonous material, water, sediment, and large wood are all delivered through intermittent stream flow. Reid and Ziemer (1994) found that intermittent channels contribute significantly to downstream reaches, as they can form a high proportion of the entire channel system in a watershed (lit. cit.). The occurrence of fish at the PIP, during drought conditions, suggests that fish could be found farther up the stream channel during seasons of high discharge such as spring run-off. The presence of fish in a stream should warrant type 3 protections, regardless of whether it is perennial or intermittent.

The extreme variability in basin size may be a function of multiple factors. The soils ability to retain water with respect to gradient, aspect, annual precipitation, and elevation will ultimately decide where perennial flow begins. Outside variables, such as agricultural water use, further increase the level of complexity associated with perennial stream flow in eastern Washington. The point of perennial flow will fluctuate as seasons change and the presence of riparian associated species in a stream channel may mirror these seasonal fluctuations. It is important that the default basin size for eastern Washington does not eliminate seasonal fish habitat on the basis of perennial flow in August.

Ideas and Suggestions

- The protocol for the PIP study relies heavily on the location of perennial flow during drought conditions. It is important to understand the relationship between low seasonal precipitation and the location of the perennial initiation points within a watershed, but it is not a healthy representation of how streams and rivers function throughout the year. In eastern Washington drought-like conditions can have a substantial affect on the perennial flow of streams and rivers. Within the STOI study area, 9 out of 15 randomly selected streams were confirmed to be dry at the mouth. The amount of water available to a watershed is assumed to be a function of the current precipitation occurring on the landscape, as well as the precipitation from previous months/years. In order to draw solid scientific conclusions regarding the relationship between stream function and forest practices we must also include data, which represents seasonal precipitation throughout the year. "Most streams and rivers have a maximum discharge during winter rains or spring snow melt", which suggests the importance of surveying perennial initiation points throughout the year (Horne and Goldman 357).

- Overall as a group we felt concerned with the date of the sample period. The group felt that peak flow should be considered as a potential time for determining perennial initiation points.
- It was also felt that due to 2001 being an unusually dry year, the perennial flow would deviate substantially from normal variations in stream hydrology.
- Vegetation is an important indicator related to aquatic environments. Elevation, precipitation, soils, and geology all reflect the type of vegetation (E+P+S+G=V). It would be beneficial to place more emphasis on the presence and absence of riparian related plant and tree species in association with the perennial initiation points. This may be the easiest way to determine the upper most extent of flowing water. Ephemeral stream flow does not usually support riparian vegetation, limiting the occurrence of riparian vegetation to sites that have a regular presence of water.
- The presence and absence of organic matter in the stream channel is an important part of the PIP survey. Evidence of heavy range cattle use can alter or mimic the appearance of native organic in-stream components. The presence of broken down fecal material often covers the native stream substrate, making it difficult to accurately classify. In addition, bankfull width and depth measurements can be

altered when cattle overuse a stream channel. Field forms should contain side notes regarding the presence/absence and severity of cattle use. This could be incorporated as part of the Poorly Defined Channel (PDC) or Modified Channel (MC) classification.

- The dry channel portion of the survey may be using valuable time, which could be used to locate and sample additional wet sites. The answer to this problem might be in noting the presence of a dry channel for 200 meters, but no data collection. However, if the data obtained from the dry channel survey is critical to Np delineation or basin size determination, a simplified version of data collection for the dry portion may be beneficial.
- The need for 200 meters of continuous visible or audible flowing water, in order to assume perennial flow to the mouth, may be moving the perennial initiation points too far down stream. The result of this is a larger basin size. Flowing water that subsurfaces and then reappears further down the stream channel should be considered perennial flow, regardless of how far it runs underground or whether you can hear it.
- Develop hydro-geomorphic associations to describe the watershed. (Developed and available through NWIFC).
- Record the Water Resource Inventory Area (WRIA) number on the field form for the segment of concern.
- Note an area on the field form to document if any fish or amphibians are present within PIP segment area.
- Note another area on the field form to record: associated seeps, springs, and wetlands and their approximate size (acreage) and relationship to the PIP.
- Standardize how precise the instream measurements need to be. Should the bankfull width/depth be rounded to the nearest tenth or hundredth? The QA/QC field auditor and PIP field crews need to be consistent.
- Segment breaks, associated with a change in gradient, should only occur when it is significant enough to result in a flow category change.
- Record the Rosgen Stream type on the field form.
- If the stream segment of concern is predominantly all agricultural land and void of any over story trees, is it warranted to eliminate the site from the PIP Survey?
- Calculating the basin size from topography breaks on a GIS based map may not be a fair representation of the actual basin size. In the field: draws, swales, and gullies, etc. that are undetectable on GIS based maps or aerial photos' may limit precipitation from entering the stream channel.

Codes for Channel Categories: DC = Defined Channel, PDC = Poorly Defined Channel, MC = Modified Channel, PC = Piped Channel, CC = Covered Channel, NC = No Channel

Back of Form B

NOTES
Seg. 1 MC Due to past logging - Corridors - organic and woody debre
At 0 meters is DC for 2 meters.
Seg. 2 appears to be a SKID TRAIL from logging. 30m of no channel.
Seg. 3 Channel covered with woody debre.
Seg. 4 At 105 m MC/culvert 2'x2' undefined channel -woody debre and organic material
Seg. 5 140m pocket of water
Seg. 8 10 yards on both side of the Stream channel are seeps. Present Boulder, cobble + gravel, Whole area on this contour is a seep.
Seg. 9 Sand/organic. Boulder in Lower part.
Seg. 12. Channel under and around vegetation head.
Seg 14 Side spring on LB Looking down stream.

NOTES; Kinkaid Creek
Downstream Survey
Start poin is located West of road, 150m past end of sharp corner,
below East facing ridge. PIP is West- southwest approx. 100m/ flagging
at road is orange and white with orange dots on west right side of road.
Seg. 8 small seep area extending 10m.
On left side of down stream direction approx. 15m from start.
Seg. 9 small seep extending 15m. On both side approx. 45m. from start
Seg. 10 seep (10 x 15m) located on right side down stream direction
approx. 75m. from start.
Seg. 11 side trib. Branches from right side of stream (down stream
direction) at 97m. From start. Tributart runs 30m. Reaching spring site.
GPS for spring N 48.17.154' W 118.54.534'
Entire stream has large amounts of large downed wood throughout.
Seg. 12 seep on right side of stream at 150m. From start
(approximately 15m x 10m in size).
